Structural Behaviour of Solid Solutions in the NdAlO₃-SrTiO₃ System

Natalia Ohon, Roman Stepchuk, Kostiantyn Blazhivskiy and Leonid Vasylechko*

Abstract

Single-phase mixed aluminates-titanates Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ ($x = 0.3 \div 0.9$) were prepared from stoichiometric amounts of constituent oxides Nd₂O₃, Al₂O₃, TiO₂ and strontium carbonate SrCO₃ by solid-state reaction technique in air at 1773 K. Crystal structure parameters of Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ were refined by full-profile Rietveld refinement in space groups $R\bar{3}c$ ($x = 0.3, 0.5, 0.7$ and 0.8) and $Pm\bar{3}m$ ($x = 0.9$). Comparison of the obtained structural parameters with the literature data for the end members of the system NdAlO₃ and SrTiO₃ revealed formation of two kinds of solid solutions Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ with the cubic and rhombohedral perovskite structure. Morphotropic rhombohedral-to-cubic phase transition in Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ series occurs at $x = 0.84$. Based on the results obtained as well as the literature data for the parent compounds, the tentative phase diagram of the NdAlO₃-SrTiO₃ pseudo-binary system have been constructed.

Keywords: Perovskite aluminates and titanates, Crystal structure, Solid solution, Phase transition

Background

Mixed aluminates-titanates with perovskite structure formed in the $RA\text{AlO}_3\text{-}AT\text{iO}_3$ pseudo-binary systems (R = rare earths, A = Sr, Ca) are prospective functional materials. In conjunction with alkaline-earth titanates, rare earth aluminates reveal excellent temperature-stable high- Q microwave dielectric properties and are widely used as radio-frequency ceramics in modern electronic devices ([1–6] and references herein). The highest Q -values among $RA\text{AlO}_3$ - and $AT\text{iO}_3$ -based microwave ceramics were reported for LaAlO₃-SrTiO₃ system, which exhibits solid solubility across the entire compositional range. It was shown that dielectric properties of mixed aluminates-titanates ceramics do not significantly depend on the nature of the rare earth and the value of resonant frequency (f_r) can be tuned by changing the concentration of solid solution. Thus potentially useful ceramics with temperature-stable relative permittivity can be obtained in other $RA\text{AlO}_3\text{-}AT\text{iO}_3$ perovskite series.

The interest to the $RA\text{AlO}_3\text{-}Sr\text{TiO}_3$ systems has been increased considerably during the last decade after discovering of the intrigue phenomena of two-dimensional electron gas at the interface between two insulators

LaAlO₃ and SrTiO₃ [7]. The interface effects occurred in the $RA\text{AlO}_3\text{-}Sr\text{TiO}_3$ perovskite systems are in the focus of active research in the field of tunable metal-insulator transition, 2D superconductivity, coexistence of superconductivity and ferromagnetism, etc. [8–11].

The aim of the present work is the study of the phase and structural behaviour of the mixed aluminates-titanates formed in the NdAlO₃-SrTiO₃ pseudo-binary system. At room temperature, the end members of the system—NdAlO₃ and SrTiO₃—adopt different variants of the perovskite structure: rhombohedral $R\bar{3}c$ and cubic $Pm\bar{3}m$, respectively. Rhombohedral NdAlO₃ transforms into the cubic perovskite structure near 2100 K ([6] and references herein), whereas strontium titanate SrTiO₃ undergoes a low-temperature (LT) phase transition from the cubic to tetragonal $I4/mcm$ perovskite structure below 105 K [12, 13]. Owing to the abovementioned peculiarities of NdAlO₃ and SrTiO₃ crystal structures, complex phase and structural behaviour is expected in the mixed neodymium-strontium aluminate-titanate system.

Methods

Mixed aluminates-titanates of nominal compositions Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ ($x = 0.3, 0.5, 0.7, 0.8, 0.9$) were prepared by solid-state reaction technique. Stoichiometric

amounts of the constituent oxides Nd_2O_3 , Al_2O_3 , TiO_2 and strontium carbonate SrCO_3 were ball-milled in ethanol for 5 h, dried, pressed into pellets and annealed in air at 1673 K for 9 h. After cooling the product, it was regrinded and repeatedly annealed at 1773 K for 9 h. X-ray powder diffraction technique (Huber imaging plate Guinier camera G670, Cu $K_{\alpha 1}$ radiation, $\lambda = 1.54056 \text{ \AA}$) was used for the phase and structural characterization of the samples at room temperature. All crystallographic calculations including full-profile Rietveld refinement were performed by using WinCSD program package [14].

Results and Discussion

Analysis of X-ray diffraction (XRD) data collected at room temperature (RT) showed that all samples synthesized adopt pure perovskite structure. No traces of foreign phases were detected (Fig. 1). Close examination of diffraction maxima revealed detectable rhombohedral deformation of the $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ samples with $x = 0.3$ and 0.5 , whereas no visible reflections splitting or deformation was observed for the specimens with higher x values (Fig. 1, inset). However, a presence of minor superstructure (113) reflection, which is indicative for rhombohedral distortion of perovskite structure, testifies that the rhombohedral structure in $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ series persists at least up to $x = 0.8$.

Full-profile Rietveld refinement of $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ structures, performed in space groups $R\bar{3}c$ and $Pm\bar{3}m$ for the samples with $x \leq 0.8$ and $x = 0.9$, respectively, entirely confirms suggested crystal structures of the specimens. Examples of graphical results of Rietveld refinement, showing excellent fits between experimental and calculated profiles of rhombohedral $\text{Nd}_{0.5}\text{Sr}_{0.5}\text{Al}_{0.5}\text{Ti}_{0.5}\text{O}_3$ and cubic

$\text{Nd}_{0.1}\text{Sr}_{0.9}\text{Al}_{0.1}\text{Ti}_{0.9}\text{O}_3$ structures are presented on Fig. 2. Refined structural parameters of all synthesized $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ samples and corresponding residuals are presented in Table 1.

Concentration dependencies of the obtained lattice parameters and unit cell volumes of $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ series in comparison with the literature data for NdAlO_3 [6] and SrTiO_3 [12] (Fig. 3) prove a formation of two kinds of solid solutions in the NdAlO_3 – SrTiO_3 pseudobinary system. Simultaneous aliovalent substitution of Sr^{2+} and Ti^{4+} species for Nd^{3+} and Al^{3+} sites reduces rhombohedral deformation in $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ series and led to morphotropic phase transition to the cubic perovskite structure at $x = 0.84$ (Fig. 3). In the related systems LaAlO_3 – SrTiO_3 and PrAlO_3 – SrTiO_3 , the phase boundary between two perovskite structures takes place above $x = 0.8$ and at $x = 0.88$, respectively [15, 16].

A decreasing structural deformation in $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ series as a consequence of increasing Goldschmidt tolerance factor with increasing x should significantly effect on the temperature of structural phase transition $R\bar{3}c - Pm\bar{3}m$, which occurs in NdAlO_3 at about 2100 K [6]. According to structural phase diagram of the related LaAlO_3 – SrTiO_3 system [15], the temperature of rhombohedra-to-cubic transition decreases almost linearly

from 850 K in “pure” LaAlO_3 to 350 K in the sample with nominal composition $\text{La}_{0.2}\text{Sr}_{0.8}\text{Al}_{0.2}\text{Ti}_{0.8}\text{O}_3$. Our recent in situ X-ray synchrotron powder diffraction investigations of the PrAlO_3 – SrTiO_3 series [16] showed that the $R\bar{3}c - Pm\bar{3}m$ transition temperature decreases gradually from 1770 K in PrAlO_3 to 930 K in $\text{Pr}_{0.5}\text{Sr}_{0.5}\text{Al}_{0.5}\text{Ti}_{0.5}\text{O}_3$ sample. Similar structure and phase behaviour at the elevated temperatures are also expected in the studied NdAlO_3 – SrTiO_3 system, tentative phase diagram of which is shown on Fig. 4. However, extrapolation of the cubic phase boundary from high-temperature region to the higher SrTiO_3 concentrations would be speculative because of the different low-temperature structures of the parent compounds NdAlO_3 and SrTiO_3 ($R\bar{3}c$ and $I4/mcm$, respectively). Evidently, phase boundary between the $R\bar{3}c$ and $I4/mcm$ structural modifications of $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ solid solution has to be

present in the SrTiO_3 -rich part of the phase diagram at low temperatures (Fig. 4). In addition, appearance of intermediate orthorhombic phase between rhombohedral $R\bar{3}c$ and tetragonal $I4/mcm$ phase fields, as it occurs in the related PrAlO_3 – SrTiO_3 [16] and NdAlO_3 – CeAlO_3 [17] systems, could not be neglected.

Comprehensive analysis of A/B-cation substitution on the antiferrodistortive phase transition $Pm\bar{3}m - I4/mcm$ in SrTiO_3 recently performed in [18] revealed that transition temperature increases in nonlinear manner with decreasing tolerance factor, depending on substituent concentration. Based on this observation, one can

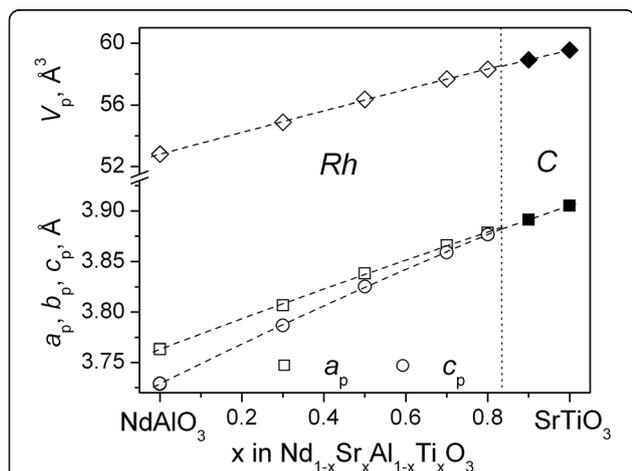

Fig. 3 Unit cell dimensions of $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ series. The rhombohedral lattice parameters are normalized to the perovskite cell as follow: $a_p = a_r/\sqrt{2}, c_p = c_r/\sqrt{12}, V_p = V_r/6$. The dotted line marks the phase boundary between the Rh and the C phases

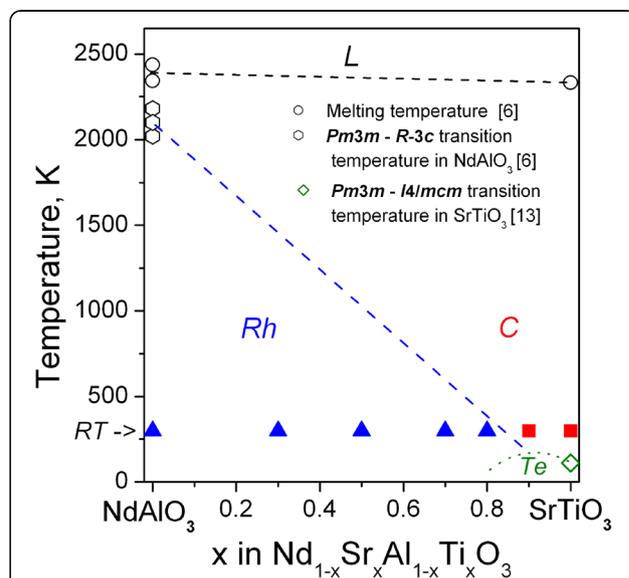

Fig. 4 Tentative phase diagram of the PrAlO_3 – SrTiO_3 pseudo-binary system. The letters L, C, Rh and Te designate liquid, cubic, rhombohedral and tetragonal phase fields, respectively. The solid symbols designate the rhombohedral (triangles) and cubic (squares) perovskite structures experimentally observed in $\text{Nd}_{1-x}\text{Sr}_x\text{Al}_{1-x}\text{Ti}_x\text{O}_3$ series at RT

predict that SrTiO₃-richest samples in the NdAlO₃–SrTiO₃ system will transform to the tetragonal *I4/mcm* structure at the temperatures higher than the pure SrTiO₃ (105 K). To shed light on the low-temperature phase behaviour in the NdAlO₃–SrTiO₃ system, thorough structural, calorimetric and spectroscopic investigations are required.

Conclusions

Continuous solid solution Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ with perovskite structure is formed in the NdAlO₃–SrTiO₃ pseudo-binary system at 1773 K. Comparison of the obtained structural parameters with corresponding data for the parent compounds NdAlO₃ and SrTiO₃ proves a decrease of perovskite structure deformation as a consequence of increasing Goldschmidt tolerance factor with increasing *x* in Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ series. As a result, concentration-induced phase transition from a rhombohedral *R* $\bar{3}c$ to the cubic perovskite structure occurs in the Nd_{1-x}Sr_xAl_{1-x}Ti_xO₃ system at *x* = 0.84. Experimental X-ray powder diffraction patterns and crystal structure parameters of rhombohedral Nd_{0.7}Sr_{0.3}Al_{0.7}Ti_{0.3}O₃ and cubic Nd_{0.1}Sr_{0.9}Al_{0.1}Ti_{0.9}O₃ phases are published by the International Centre of Diffraction Data (ICDD) in the last release of the Powder Diffraction Files (PDF cards NN 00-066-0395 and 00-066-0396, respectively) [19].
